

M2D5:
Isolate pgRNA, Co-transform E. coli,
Confirm pgRNA sequence

10/27/2016 and 10/28/2016

M2 experimental overview:

M2D5 experimental overview:

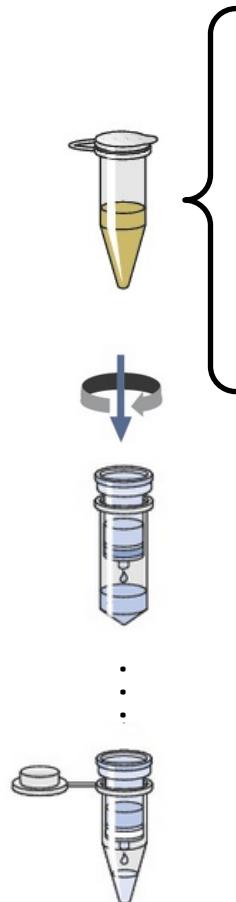

Today, you have three goals:

- 1.) Isolate your gRNA plasmid from *E. coli* cultures
- 2.) Co-transform your plasmid with pdCas9 into MG1655 cells
- 3.) Submit gRNA plasmid for sequencing to confirm product

Mini-preps isolate plasmids from bacteria

Mini-prep to isolate DNA

steps	contents	purpose
prepare P1	Tris/EDTA buffer RNase	Resuspension buffer, EDTA - block DNase activity, RNase - get rid of RNA
lyse P2	SDS NaOH	solubilize proteins, denature DNA
neutralize N3	acetic acid, chaotropic salt, potassium acetate	Neutralizes solution, renature plasmid DNA
spin		separate soluble from insoluble
bind	silica column	concentrate DNA
wash PB, PE	ethanol	** get rid of <i>all</i> ethanol
elute	water, pH 8.0	Elute all DNA off column

Review of mini-prep: Lysis with SDS/NaOH

1. Sodium dodecyl sulfate (SDS)

- dissolves membranes

- binds to and denatures proteins

2. Sodium hydroxide (NaOH)

- denatures DNA

Because plasmids are supercoiled, both DNA strands remain entangled after denaturation

Review of mini-prep: Neutralization

1. Acetic acid / potassium acetate solution

- neutralizes NaOH (renatures plasmid DNA)
- converts soluble SDS into insoluble PDS (white fluff)

2. Chaotropic salt

- facilitates DNA binding to silica

➤ After centrifugation

- supernatant: plasmid DNA (and soluble cellular constituents)
- pellet: PDS, lipids, proteins, chromosomal DNA

Review of mini-prep: Bind DNA to column

- Washes with PB and PE
 - remove residual contaminants (eluent)
 - maintain DNA onto column

Review of mini-prep: Elution with water

- Water competes DNA off of column

Your CRISPRi system requires the use of two plasmids

- Target gene
- pgRNA_target
- pdCas9

Transform MG1655 competent cells with both plasmids

- made **competent** by CaCl₂
 - Ca²⁺ ions attract both DNA and lipopolysaccharide (LPS)
 - heat shock negatively charged inner core
- in exponential growth phase
 - OD₆₀₀ = 0.4-0.8
- handle very gently, or will lyse
 - *on ice* all the time, and with chilled solutions **
 - not vortexed **

A few brief notes on *E. coli* growth curve

OD = optical density)

- exponential phase
 - binary fission
 - OD600 ~ 0.4 - 0.8
 - machinery ready
- OD ≠ absorbance
 - measuring turbidity (light scattering)
 - don't absorb at 600nm (yellowish)
 - UV is damaging to cells

MG1655 needs to be co-transformed with both pdCas9 and pgRNA

pdCas9 confers resistance to: chloramphenicol

pgRNA confers resistance to: ampicillin

Do we have the intended gRNA sequence?

- Diagnostic digests
- Sequencing
 - good to have both F and R primers
 - double check everything
 - coverage (~1Kb limit)
 - di-deoxynucleotides terminate elongation

Sanger sequencing by Genewiz

① Reaction mixture

- ▶ Primer and DNA template
- ▶ DNA polymerase
- ▶ ddNTPs with flouochromes
- ▶ dNTPs (dATP, dCTP, dGTP, and dTTP)

② Primer elongation and chain termination

③ Capillary gel electrophoresis separation of DNA fragments

④ Laser detection of flouochromes and computational sequence analysis

chromatogram

Tips to write Methods (due M2D7)

- Use subsections with descriptive titles
 - Put in logical order
 - Begin with topic sentence to introduce purpose
- Use clear and concise full sentences
 - Eliminate tables and lists
 - Passive voice expected
- Use the most flexible units
 - Write concentrations (when known) rather than volumes
- Eliminate '109 specific details
 - Do not include details about tubes and water!
 - Assume reader has some microbiology experience

Improving your Methods [1]

Template DNA (5 μ L) and primers were mixed with 20 μ L of

2.5X Master Mix in a PCR tube. Water was added to 50 μ L.

A tube without template was prepared and labeled control.

- no tubes
- no volumes (final concentrations)
- don't include no template control
- Master mix - what is it? where is it from? etc.
- don't need to say you added water
- What is the template
- What are the primer sequences (5' - NNN - 3')
- Thermocycler - temps and times

Improving your Methods [2]

A liquid bacteria culture was pelleted and the DNA was purified using a Qiagen kit.

Improved Methods

[1] *PCR amplification of inverse pericam (IPC)*

Inverse pericam (IPC) was amplified from a pcDNA3-IPC template (5 ng/uL) with 2 pmol/uL IPC-forward (5' NNN 3') and IPC-reverse (5' NNN 3') primers, using 1X MasterMix (company, city, state/country) and the following thermocycler conditions: initial denaturation at 98°C for 30 s, 25 cycles of amplification (melt at 98°C for 10 s, anneal at 55°C for 30 s, extend at 72°C for 2 min), final extension at 72°C for 2min.

[2] *Site-directed mutagenesis and amplification of the pRSET-IPC plasmid*

Introductory topic sentence. SDM (including KLD, transformation in NEB5α)

The DNA of a 1.5 mL of NEB 5alpha (genotype: *fhuA2 Δ(argF-lacZ)U169 phoA glnV44 Φ80 Δ(lacZ)M15 gyrA96 recA1 relA1 endA1 thi-1 hsdR17*) overnight** culture was collected using a QIAquick mini-prep kit (Qiagen, Hilden, Germany) according to the manufacturer's protocol with a final elution in 30 μL of distilled water pH 8.0.

Confirmation of intended mutation by sequencing (Genewiz, Cambridge, MA)

**grown to saturation (as opposed to exponential growth phase for transformation or induction of protein)
