# Resolving Power of Microscopes

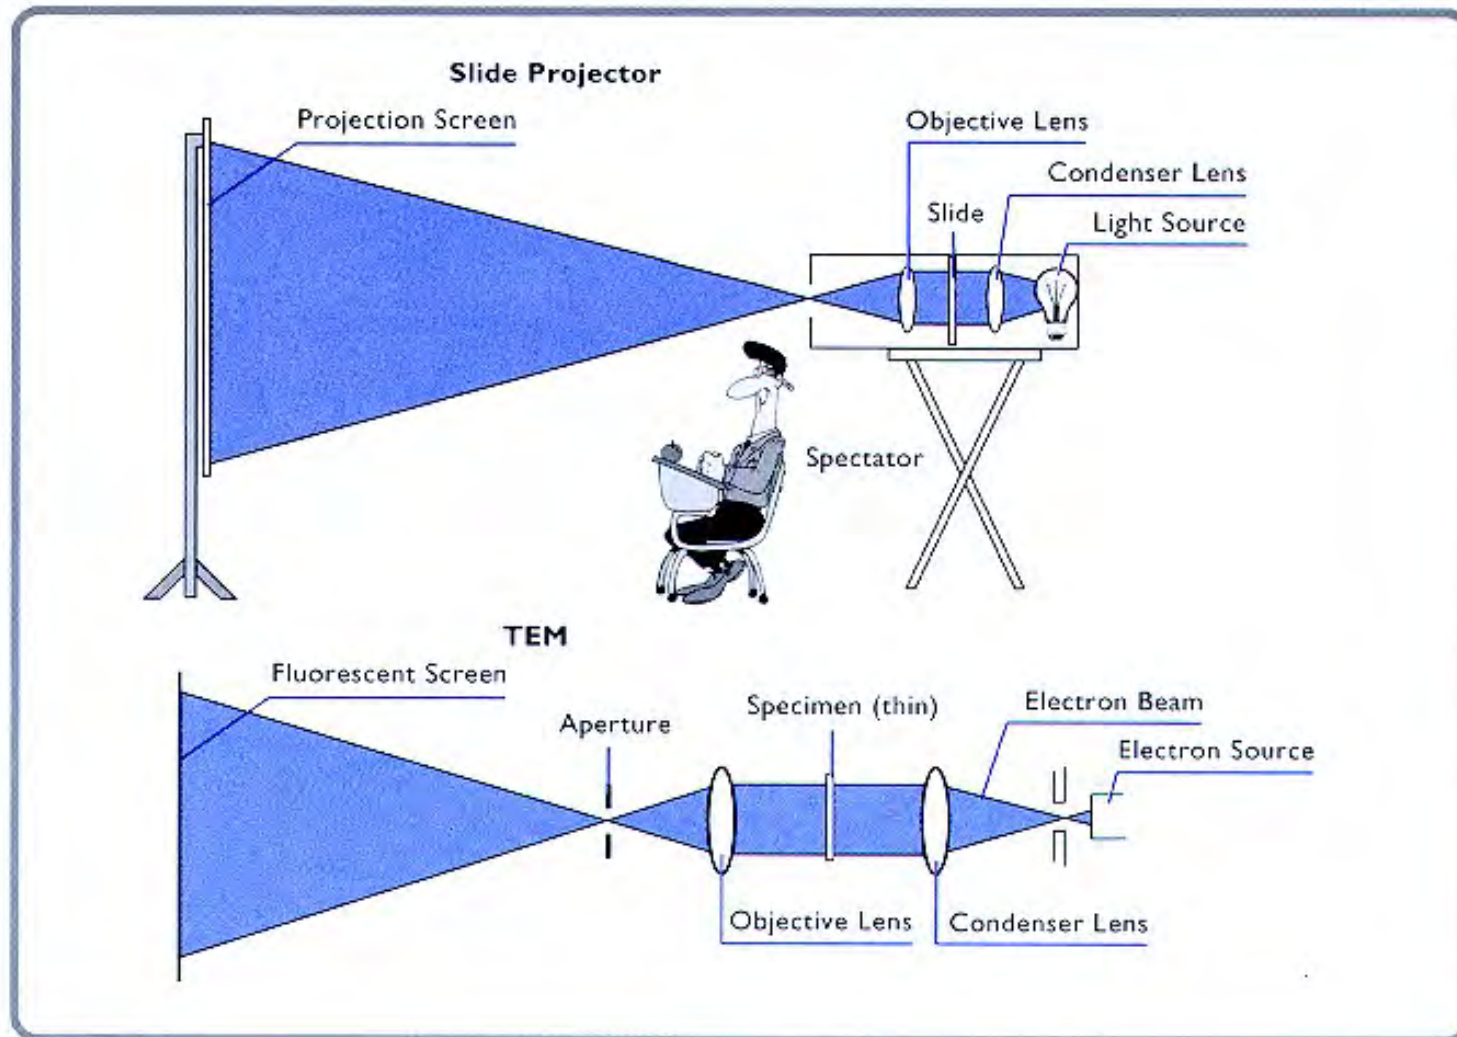

# What's TEM

---

- An electron-optical microscope that uses electromagnetic lenses to focus and direct an electron beam.
- Bright field imaging is from electrons interacting with electron dense materials to cast a shadow on a screen or camera.
- High voltages between 10KV and 1MV. The higher the voltage is, the shorter the wavelength of electrons, giving the better resolution. **200KV.** ultimate point-to-point resolution of 0.19 nm

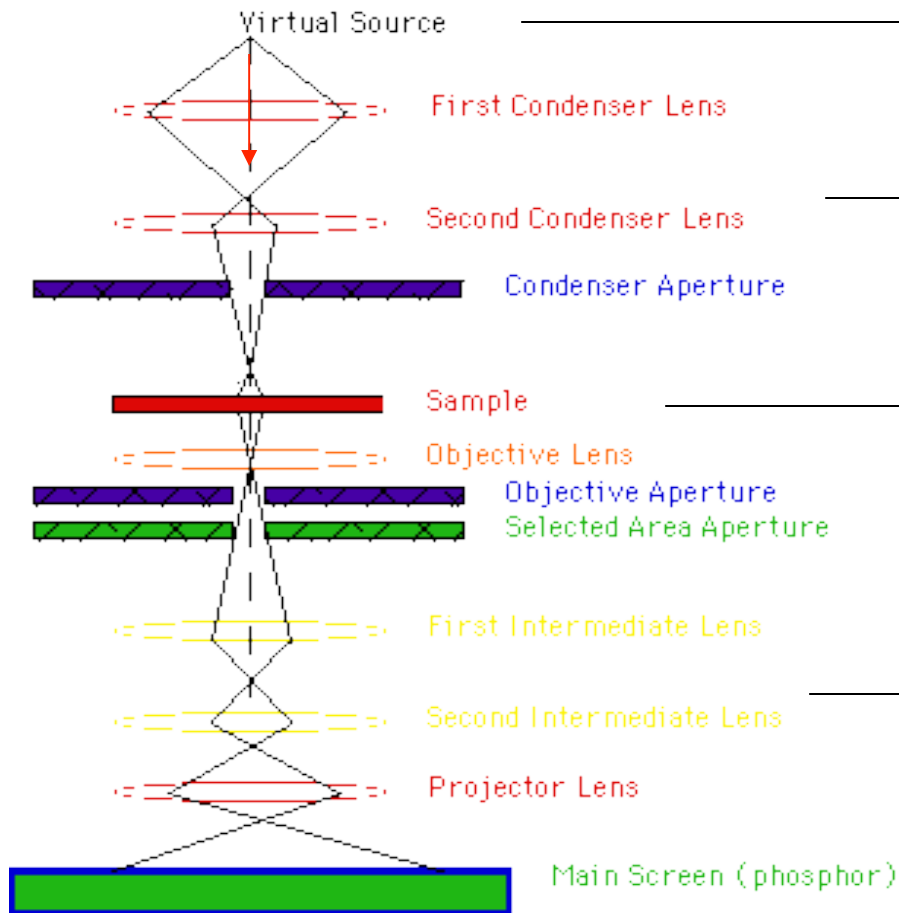

<http://labs.mete.metu.edu.tr/tem/TEMtext/TEMtext.html>

# What's TEM

## Electron beam path

Source is a beam of high velocity electrons

Lanthanum hexaboride cathode

Electron beam focused by condenser lens onto specimen

If a sample is thin enough, electron beam can pass through it

Transmission/scattering beam is focused by objective lens/intermediate/projection lens. Final image/electron diffraction pattern forms on a screen for viewing

# Why We Need TEM

---

The main use of the TEM is to examine the microstructure structure, composition, and properties of specimens in ways that cannot be examined using other equipment or techniques.

## **Morphology (Bright Field Image, Dark Field , HRTEM)**

- The size, shape, morphology, and distribution of the particles as well as their relationship to each other on the scale of atomic diameters.
- Contrast comes from electrons interacting with electron dense atoms in the sample, the scattered electrons cause a shadow to be cast on the camera or screen.
- Crystalline samples scatter more electrons than noncrystalline samples, so **amorphous samples have less contrast** than crystalline samples

# Why We Need TEM

- **Crystallographic Information (Electron Diffraction, HRTEM)**
  - For crystalline samples, crystal structure, degree of ordering, and detection of atomic-scale defects in areas a few nanometers in diameter can be determined
- **Compositional Information (Energy dispersive spectroscopy (EDX), Electron energy loss spectroscopy (EELS), Scanning TEM (STEM))**
  - The elements and compounds the sample is composed of and their relative ratios, in areas a few nanometers in diameter

# What's TEM

Different equipment in TEM is then used to collect scattered electrons produced by the specimen-electron interaction, giving different types of information

} Compositional Information

} Morphology & Crystallographic Information

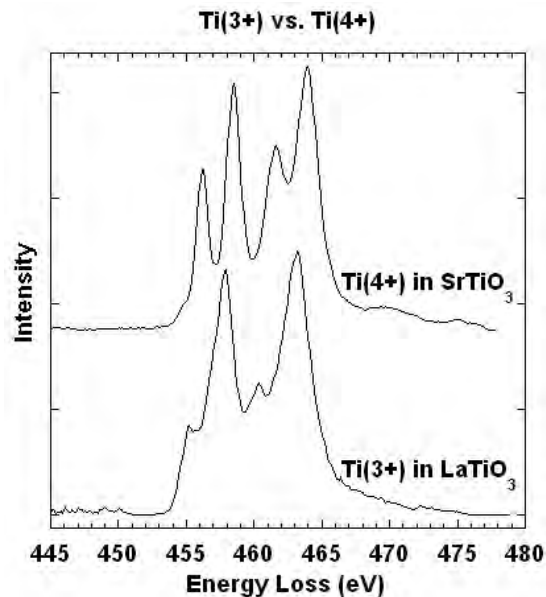

# Elemental mapping and information

- Elemental mapping can be done by two methods, STEM and EELS
- STEM involves rastering an electron beam through a sample and determining the elemental composition of each spot by either X-ray analysis or EELS (element specific)

# Elemental Analysis

- The  $e^-$  beam has the energy to remove core electrons
- This causes for a measurable loss of energy in the electron beam (EELS)
- And also for the emission of X-rays (EDX)
- Both techniques are element specific and can be combined to show images that isolate where each element is present in the sample

EELS of Titanium particles shows a difference between  $\text{Ti}^{3+}$  and  $\text{Ti}^{4+}$

EDX of  $\text{BaSrO}_x$  shows all the elements present in the sample

Incident Radiation from  
Primary X-ray Source

## Energy Dispersive X-ray Spectroscopy (EDXS)

Different elements emit different characteristic X-rays when excited by an electron beam. These X-rays can be used to identify the elements present, quantify their relative or absolute concentration, and map their distribution.

Different elements cause incident electrons to lose different amounts of energy. EELS can be used to identify the elements present, quantify their relative or absolute concentration, and map their distribution. Since the absorption of energy from incident electrons is dependent on the bonding of the elements present, EELS can also probe the structure of the material.

# JEOL 2010 Field Emission Gun(FEG) TEM

2010FEG TEM Photo

2010FEG TEM Schematic Diagram

## 2010FEG TEM Characteristics

1. **Point Resolution** : less than 0.2nm
2. **Brightness** : 2-order higher brightness than with the LaB6 electron gun,(JEOL 2010 TEM)  
3-order higher with tungsten thermionic gun(JEOL 200CX TEM)
3. **Nanoanalysis** : Atomic arrangement, Grain Size, Crystal Orientation, Defects,  
Chemical analysis - elements, composition
